31 August–04 September 2026

Motivating example

Code of a loop representing ~10% walltime

```
do j = ni + nvalue1, nato

    nj1 = ndim3d*j + nc ; nj2 = nj1 + nvalue1 ; nj3 = nj2 + nvalue1
    u1 = x11 - x(nj1) ; u2 = x12 - x(nj2) ; u3 = x13 - x(nj3)
    rtest2 = u1*u1 + u2*u2 + u3*u3 ; cnij = eci*qEold(j)
    rij = demi*(rvwi + rvwalc1(j))
    drtest2 = cnij/(rtest2 + rij) ; drtest = sqrt(drtest2)
    Eq = qq1*qq(j)*drtest
    ntj = nti + ntype(j)
    Ed = ceps(ntj)*drtest2*drtest2*drtest2
    Eqc = Eqc + Eq ; Ephob = Ephob + Ed
    gE = (c6*Ed + Eq)*drtest2 ; virt = virt + gE*rtest2
    u1g = u1*gE ; u2g = u2*gE ; u3g = u3*gE
    g1c = g1c - u1g ; g2c = g2c - u2g ; g3c = g3c - u3g
    gr(nj1, thread_num) = gr(nj1, thread_num) + u1g
    gr(nj2, thread_num) = gr(nj2, thread_num) + u2g
    gr(nj3, thread_num) = gr(nj3, thread_num) + u3g

end do
```

Where are the bottlenecks?

Motivating example

Code of a loop representing ~10% walltime

The diagram shows a code loop with several annotations pointing to specific parts of the code:

- 1) High number of statements:** A vertical box on the left side of the code block.
- 2) Non-unit stride accesses:** Two annotations. One points to the `do j = ni + nvalue1, nato` line. The other points to the `gr(nj1, thread_num) = gr(nj1, thread_num) + u1g`, `gr(nj2, thread_num) = gr(nj2, thread_num) + u2g`, and `gr(nj3, thread_num) = gr(nj3, thread_num) + u3g` lines.
- 3) Indirect accesses:** Points to the `ceps(ntj)*drtest2*drtest2*drtest2` line.
- 4) DIV/SQRT:** Points to the `sqrt(drtest2)` line.
- 5) Reductions:** Points to the `virt = virt + gE*rtest2` line.
- 6) Variable number of iterations:** Points to the `do j = ni + nvalue1, nato` line.

```

do j = ni + nvalue1, nato
  nj1 = ndim3d*j + nc ; nj2 = nj1 + nvalue1 ; nj3 = nj2 + nvalue1
  u1 = x11 - x(nj1) ; u2 = x12 - x(nj2) ; u3 = x13 - x(nj3)
  rtest2 = u1*u1 + u2*u2 + u3*u3 ; cnij = eci*qEold(j)
  rij = demi*(rvwi + rvwalc1(j))
  drtest2 = cnij/(rtest2 + rij) ; drtest = sqrt(drtest2)
  Eq = qq1*qq(j)*drtest
  ntj = nti + ntype(j)
  Ed = ceps(ntj)*drtest2*drtest2*drtest2
  Eqc = Eqc + Eq ; Ephob = Ephob + Ed
  gE = (c6*Ed + Eq)*drtest2 ; virt = virt + gE*rtest2
  u1g = u1*gE ; u2g = u2*gE ; u3g = u3*gE
  g1c = g1c - u1g ; g2c = g2c - u2g ; g3c = g3c - u3g
  gr(nj1, thread_num) = gr(nj1, thread_num) + u1g
  gr(nj2, thread_num) = gr(nj2, thread_num) + u2g
  gr(nj3, thread_num) = gr(nj3, thread_num) + u3g
end do
  
```

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations

Which is the dominant one?

➔ Need analysis tools to identify performance issues

A multifaceted problem

What type of problems are we facing?

- Identifying the dominant issues: Algorithm, implementation, parallelisation, compilation, ...
 - CPU or data access problems
- Making the **best use** of the machine features

What levers do we have to address them?

- Compiler switches, Partial/full vectorization
- Loop blocking/array restructuring, If removal, Full unroll
- Binary transforms (prefetch)
- ...

Which issues will be the most rewarding to fix?

- **40%** total time, expected **10%** speedup
 - → TOTAL IMPACT: **4%** speedup
- **20%** total time, expected **50%** speedup
 - → TOTAL IMPACT: **10%** speedup

→ **Need for dedicated and complementary tools**

Our Approach

Nobody wants problems everybody wants solutions ☺

- Focusing on the knobs that code developers can operate:
 - Compiler flags and runtime settings
 - Code restructuring
 - Data restructuring
 - Assisting the user in using these knobs
- ➔ **In addition to pinpointing problems, guiding the user towards a way to address them.**

Philosophy: Analysis at Binary Level

- Compiler optimizations increase the distance between the executed code and the source code
- Source code instrumentation may prevent the compiler from applying certain transformations
- Allows to be agnostic with regard to compiled source code language

➔ **What You Analyse Is What You Run**

MAQAO: Modular Assembly Quality Analyzer and Optimizer

Objectives:

- Characterizing performance of HPC applications
- Focusing on performance at the **core/node level**
- **Guiding users** through the optimization process
- Estimating return on investment (**R.O.I.**)

Characteristics:

- **Modular tool** offering complementary views
- Support for **x86-64** and **aarch64** (beta version)
 - Working prototype for AMD GPU
- LGPL3 Open Source software
- Developed at UVSQ since 2004
- Binary release available as a **static executable**

Success stories

Optimizing industrial and academic HPC applications:

- QMC=CHEM (IRSAMC)
 - Quantum chemistry
 - Speedup: **> 3x**
 - Optimization: moved invocations of functions with identical parameters out of the loop body
- Yales2 (CORIA)
 - Computational fluid dynamics
 - Speedup: **up to 2.8x**
 - Optimization: removing double structure indirections
- Polaris (CEA)
 - Molecular dynamics
 - Speedup: **1.5x – 1.7x**
 - Optimization: enforcing loop vectorization through compiler directives
- AVBP (CERFACS)
 - Computational fluid dynamics
 - Speedup: **1.08x – 1.17x**
 - Replaced divisions by reciprocal multiplications
 - Complete unrolling of loops with a small number of iterations

Partnerships

MAQAO is part of the POP Centre of Excellence

- Provides performance optimisation and productivity services for academic and industrial codes
- <https://pop-coe.eu/>

MAQAO has been funded by UVSQ, Intel and CEA (French department of energy) through Exascale Computing Research (ECR) and through various European projects (FUI/ITEA: H4H, COLOC, PerfCloud, ELCI, POP2 CoE, TREX CoE, etc...)

Provided core binary analysis and instrumentation capabilities and features for other tools:

- TAU performance tools with MADRAS patcher through MIL (MAQAO Instrumentation Language)
 - X86_64 only, aarch64 under development
- Intel Advisor

MAQAO team and collaborators

MAQAO Team

- William Jalby, Prof.
- Cédric Valensi, Ph.D.
- Emmanuel Oseret, Ph.D.

- Email: contact@maqao.org

Useful notions

SIMD/Vectorization/Data Parallelism

- Scalar pattern: $a[i] = b[i] + c[i]$
- Vector pattern: $a(i, i + 8) = b(i, i + 8) + c(i, i + 8)$
- Benefits : increases memory bandwidth and **IPC**
- Example implementations :
 - ARM : Neon, SVE
 - x86 : SSE, AVX, AVX512

FMA/MAC

- Fused-Multiply-Add
- Multiply-Accumulate

Memory and caches

- Computations are in general faster than memory accesses
- Alignment/Contiguity of memory (x86) :
posix_memalign, aligned_alloc, ...
- Caches: L1, L2, L3, ...

Scalar addition

FMA

Vector addition

Aligned memory access

Crossing cacheline boundary

Unaligned memory access

MAQAO Main Features

Binary layer

- Builds internal representation from binary
 - Construct high level structures (CFG, DDG, SSA, ...)
 - Links binary instructions to source code
 - Δ A single source loop can be compiled as multiple assembly loops → Affecting unique identifiers to loops
- Allows patching through binary rewriting

Profiling

- LProf: Lightweight sampling-based Profiler operating at process, thread, function and loops level

Static analysis

- CQA (Code Quality Analyzer): Evaluates the quality of the binary code and offers hints for improving it

Performance view aggregation module: ONE View

- Goal: Guiding the user through the analysis & optimization process.
- Synthesizes information provided by different MAQAO modules
- Automatizes execution of experiments invoking other MAQAO modules and aggregates their results to produce high-level reports in HTML or XLSX format

MAQAO CQA: Code Quality Analyzer

Goal: Assist developers in improving code performance

Features:

- Static analysis: no execution of the application
- Allows cross-analysis of/on multiple architectures
- Evaluates the quality of compiler generated code
- Proposes hints and workarounds to improve quality/performance
- Loops centric
 - In HPC, loops cover most of the processing time
- Targets compute-bound codes

Vectorization

Your loop is not vectorized. 8 data elements could be processed at once in vector registers.

By vectorizing your loop, you can lower the cost of an iteration from 40.00 to 5.00 cycles (8.00x speedup).

Details

All SSE/AVX instructions are used in scalar version (process only one data element in vector registers). Since your execution units are vector units, only a vectorized loop can use their full power.

Workaround

- Try another compiler or update/tune your current one:
 - recompile with fassociative-math (included in Ofast or ffast-math) to extend loop vectorization to FP reductions.
- Remove inter-iterations dependences from your loop and make it unit-stride:
 - If your arrays have 2 or more dimensions, check whether elements are accessed contiguously and, otherwise, try to permute loops accordingly: C storage order is row-major: for(i) for(j) a[j][i] = b[j][i]; (slow, non stride 1) => for(i) for(j) a[i][j] = b[i][j]; (fast, stride 1)

- If your loop streams arrays of structures (AoS), try to use structures of arrays instead (SoA): for(i) a[i].x = b[i].x; (slow, non stride 1) => for(i) a.x[i] = b.x[i]; (fast, stride 1)

CQA Performance Predictions: “What If” Scenarios

Objective: Provide optimistic speedups if a given optimization was applied to a loop

- For each optimization, CQA will generate the corresponding ideal assembly code and compute its speedup compared to the original
- These “What If Scenarios” are generated in a fully static manner.

No Scalar Integer: keep only FP Arithmetic and Memory operations, suppress all others

- Scenario: Perfect data access (no address computations)

FP Vectorised: only replace scalar FP Arithmetic by Vector FP Arithmetic equivalent. Generate additional instructions to fill in Vector Registers.

- Scenario: All FP operations successfully vectorised

Fully Vectorised: replace both scalar FP Arithmetic and FP Load/Store by their Vector equivalent.

- Scenario: All operations successfully vectorised

Application to Motivating Example

Issues identified by CQA

CQA can detect and provide hints to resolve most of the identified issues:

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations
- 7) Vector vs scalar

MAQAO ONE View: Performance View Aggregator

Automating the whole analysis process

- Takes care of invoking successive MAQAO modules
- Generate aggregated performance views
- Generate a report in HTML format

Main steps:

- Invokes LProf to identify hotspots
- Invokes CQA to analyse hotspots

Available results:

- Speedup predictions
- High-level summary
- Global performance metrics
- Hints for improving performance
- Parallel efficiency analysis

ONE View Reports Levels

ONE View ONE

- Requires a single run of the application
- Profiling of the application using LProf
- Static analysis using CQA

Scalability mode

- Multiple executions with varying parallel configurations
- Allows to evaluate scalability or parallel behaviour of applications

Comparison mode

- Comparison of multiple runs (iso-binary or iso-source)
- Allows to compare performance across different datasets, compilers, or hardware platforms

Stability mode

- Multiple runs with identical parameters
- Allows to assess the stability of execution time

Analysing an application with MAQAO

ONE View execution

- Provide all parameters necessary for executing the application
 - Parameters can be passed on the command line or as a configuration file
 - Parameters include executable name, MPI commands, dataset directory, ...

```
$ maqao oneview --create-report=one --mpi_command="mpirun -n 16" -- bt-mz.C.x
```

OR

```
$ maqao oneview --create-report=one --config=my_config.json"
```

- ONE View can reuse an existing experiment directory to perform further analyses
- Results available in HTML format by default
 - XLS spreadsheets and textual output generation are also available

Online help is available:

```
$ maqao oneview --help
```

Thank you for your attention !

Questions ?

Navigating ONE View Reports

ONE View main tabs

- ONE View reports are organised among tabs, each regrouping different sets of information

The screenshot shows the MAQAO ONE View interface. The top navigation bar contains the MAQAO logo and several tabs: Global, Summary, Application, Functions, Loops, and Topology. A gear icon for style selection is on the right. Red arrows point from descriptive text boxes to each tab. The Global tab is active, showing a table of metrics and a speedup summary graph.

Global metrics characterizing the application and estimating the impact of standard optimisations

High-level summary evaluating the quality of the experiment and complexity for solving the main optimisation issues

Detailed metrics on the application behaviour

Functions profile

Loops profile and analyses

Reports on application topology and affinity

Style selection

Global Summary Application Functions Loops Topology

kripke_aocc_v2 - 2025-03-27 14:40:57 - MAQAO 2.21.4

Help is available by moving the cursor above any ? symbol or by checking [MAQAO website](#).

► Filter Information

Global Metrics ?		CQA Potential Speedups Summary
Total Time (s)	19.87	
Max (Thread Active Time) (s)	18.44	
Average Active Time (s)	18.40	
Activity Ratio (%)	100	
Average number of active threads	101.560	

Global tab

Global metrics on the application general behaviour

Maximal speed-ups at application level for various ideal optimisations

Experimental condition: system characteristics, parallelisation, application compilation flags, ...

Graphs associated to some of the metrics or speed-ups from the two leftmost panels.

Recap of ONE View configuration

Navigating Global Tab

Hovering over a question mark in a panel header displays a tooltip describing the content of the panel

Hovering over a metric name displays a tooltip describing the metric

When hovering over a metric, a small blue bar appearing on the left means that clicking on the metric will cause a graph to appear on the rightmost panel

Global Tab Metrics

Experiment summary

- Machine characteristics and configuration

Global metrics

- General quality metrics derived from MAQAO analyses
- Global speedup predictions
 - Speedup prediction depending on the number of vectorised loops
 - Ordered speedups to identify the loops to optimise first

Time Categorisation

Available from the Global Tab and Application Tab

Objective: Identifying at a glance where time is spent

- Application
 - Main executable
- Parallelization
 - Threads
 - OpenMP
 - MPI
- System libraries
 - I/O operations
 - String operations
 - Memory management functions
- External libraries
 - Specialised libraries such as libm / libmkl
 - Application code in external libraries

Application Categorization

Summary Tab

Displays an evaluation of the quality of the analysis performed by ONE View. Red items signal issues that could require a rerun of the analysis with the suggested new parameters

Displays an evaluation of the overall optimisation of the code and the expected pitfalls that will be encountered when trying to optimise it.

- The first two tabs will be open by default only if they contain at least one red item

Displays for the hottest loops a list of performance issues and the estimated complexity of their resolutions

Stylizer

- [4 / 4] Application profile is long enough (18.44 s)
To have good quality measurements, it is advised that the application profiling time is greater than 10 seconds.
- [3 / 3] Optimization level option is correctly used
- [3.00 / 3] Most of time spent in analyzed modules comes from functions compiled with -g and -fno-omit-frame-pointer
-g option gives access to debugging informations, such as source locations. -fno-omit-frame-pointer improve the accuracy of callchains found during the application profiling.
- [3 / 3] Host configuration allows retrieval of all necessary metrics.
- [0 / 3] Compilation of some functions is not optimized for the target processor
Architecture specific options are needed to produce efficient code for a specific processor (-x(target) or -ax(target)).
- [2 / 2] Application is correctly profiled ("Others" category represents 0.02 % of the execution time)
To have a representative profiling, it is advised that the category "Others" represents less than 20% of the execution time in order to analyze as much as possible of the user code
- [1 / 1] Lstopo present. The Topology lstopo report will be generated.
- [0 / 0] Fastmath not used
Consider to add ffast-math to compilation flags (or replace -O3 with -Ofast) to unlock potential extra speedup by relaxing floating-point computation consistency. Warning: floating-point accuracy may be reduced and the compliance to IEEE/ISO rules/specifications for math functions will be relaxed, typically 'errno' will no longer be set after calling some math functions.

Strategizer

- [4 / 4] Enough time of the experiment time spent in analyzed loops (94.10%)
If the time spent in analyzed loops is less than 30%, standard loop optimizations will have a limited impact on application performances.
- [4 / 4] CPU activity is good
CPU cores are active 100.00% of time
- [4 / 4] Threads activity is good
On average, more than 99.78% of observed threads are actually active
- [4 / 4] Affinity is good (100.00%)
Threads are not migrating to CPU cores: probably successfully pinned
- [4 / 4] Loop profile is not flat
At least one loop coverage is greater than 4% (66.79%), representing an hotspot for the application
- [4 / 4] Enough time of the experiment time spent in analyzed innermost loops (27.12%)
If the time spent in analyzed innermost loops is less than 15%, standard innermost loop optimizations such as vectorisation will have a limited impact on application performances.
- [0 / 3] Cumulative Outermost/In between loops coverage (66.98%) greater than cumulative innermost loop coverage (27.12%)
Having cumulative Outermost/In between loops coverage greater than cumulative innermost loop coverage will make loop optimization more complex
- [3 / 3] Less than 10% (0.00%) is spend in BLAS1 operations
It could be more efficient to inline by hand BLAS1 operations
- [2 / 2] Less than 10% (0.00%) is spend in BLAS2 operations
BLAS2 calls usually could make a poor cache usage and could benefit from inlining.
- [2 / 2] Less than 10% (0.00%) is spend in Libm/SVML (special functions)

Optimizer

Loop ID	Analysis	Penalty Score
▶ Loop 774 - kripke_aocc.v2	Execution Time: 66 % - Vectorization Ratio: 16.25 % - Vector Length Use: 14.14 %

▶ Loop 1308 - kripke_aocc_v2	Execution Time: 0 % - Vectorization Ratio: 0.00 % - Vector Length Use: 12.28 %	

Click the triangle to expand and show all performance issue for a loop

A "+" sign appears when hovering over a line, which allows to expand all at once

Application Tab

Click on an option to display the corresponding graph on the rightmost panel

Hovering over a question mark near an option displays a tooltip describing the associated information

Click the triangle to show the loops contained in a function or a loop

Expand this tab to view options for restricting the displayed functions by the library containing them

Check the boxes to select which columns to display. The buttons allow to select/deselect groups of similar boxes at once

Right-click on a line to get a contextual menu allowing to display load balancing graph and callchains for this function or loop

Functions and Loops

23 loops and 95 functions have been discarded from the report because their coverage is lower than the threshold set by *object_coverage_threshold* (0.01%). It represents about 0.07% of the application. To include them, change the value of *object_coverage_threshold* in the experiment directory configuration file, then rerun the command with the additional parameter --force-static-analysis.
Inclusive metrics are only related to the given object code and do not include other external objects / libraries.

Click this button to restrict the display to innermost/single loops

Expand this tab to view options for restricting the displayed loops by the library containing them

Check the boxes to select which columns to display. The buttons allow to select/deselect groups of similar boxes at once

Hover over a loop Source Location (resp. Source Function) to display in a tooltip the full list of its sources (resp. full name of the function containing it)

Loops Index

23 loops have been discarded from the report because their coverage is lower than the threshold set by *object_coverage_threshold* (0.01%). It represents about 0.03% of the application. To include them, change the value of *object_coverage_threshold* in the experiment directory configuration file, then rerun the command with the additional parameter *--force-static-analysis*

Vectorization

Your loop is probably not vectorized. Only 14% of vector register length is used (average across all SSE/AVX instructions) in your loop, you can lower the cost of an iteration from 2.75 to 0.27 cycles (10.35x speedup).

Details

Store and arithmetical SSE/AVX instructions are used in scalar version (process only one data element in vector register) execution units are vector units, only a vectorized loop can use their full power.

Workaround

- Try another compiler or update/tune your current one:
 - recompile with ffast-math (included in Ofast) to extend loop vectorization to FP reductions.
- Remove inter-iterations dependencies from your loop and make it unit-stride:
 - If your arrays have 2 or more dimensions, check whether elements are accessed contiguously and, otherwise, re-order loops accordingly: C storage order is row-major: for(i) for(j) a[j][i] = b[j][i]; (slow, non stride 1) => for(i) for(j) a[i][j] = b[i][j]; (fast, stride 1)

Logical mapping
j=1, 2, 3
i=1

90:  >  - mblock(4,5) * mblock(5,1)
91:  >  cblock(5,1) = cblock(5,1) - mblock(5,1) * mblock(1,1)
92:  >  - mblock(5,2) * mblock(2,1)
93:  >  - mblock(5,3) * mblock(3,1)
94:  >  - mblock(5,4) * mblock(4,1)
95:  >  - mblock(5,5) * mblock(5,1)
96:  >  cblock(1,2) = cblock(1,2) - mblock(1,2) * mblock(1,1)
97:  >  - mblock(1,3) * mblock(2,1)
98:  >  - mblock(1,4) * mblock(3,1)
99:  >  - mblock(1,5) * mblock(4,1)
100: >  - mblock(1,6) * mblock(5,1)
101: >  cblock(2,2) = cblock(2,2) - mblock(2,2) * mblock(1,1)
102: >  - mblock(2,3) * mblock(2,1)
103: >  - mblock(2,4) * mblock(3,1)
104: >  - mblock(2,5) * mblock(4,1)

```

The right pane displays the analysis results:

- Coverage:** 4.79%
- Function:** [matmul_sub](#)
- Source file and lines:** solve_subs.f:71-175
- Module:** bt-mz.C.16
- The loop is defined in:** /ccc/dsk/nfs-server/user/cont001/occe/valensic/NPB3.3-1-MZ/NPB3.3-MZ-MPI/BT-MZ/solve_subs.f:71-175.
- It is main loop of related source loop which is unrolled by 2 (including vectorization).**
- gain potential hint expert** tabs are visible.
- Code clean check:** Detected a slowdown caused by scalar integer instructions (typically used for address computation). By removing them, you can lower the cost of an iteration from 27.00 to 25.00 cycles (1.08x speedup).
- Workaround:** (Link to a detailed report)
- FMA:** Presence of both ADD/SUB and MUL operations. **Workaround:** (Link to a detailed report)
- Type of elements and instruction set:** 195 SSE or AVX instructions are processing arithmetic or math operations on double precision FP elements in scalar mode (one at a time).
- Matching between your loop (in the source code) and the binary loop:** The binary loop is composed of 195 FP arithmetical operations:
 - 70: addition or subtraction
 - 125: multiply
 The binary loop is loading 1760 bytes (220 double precision FP elements). The binary loop is storing 1632 bytes (204 double precision FP elements).
- Arithmetic intensity:** Arithmetic intensity is 0.06 FP operations per loaded or stored byte.
- Unroll opportunity:** Loop is data access bound. **Workaround:** Unroll your loop if trip count is significantly higher than target unroll factor and if some data references are common to consecutive iterations. This can be done manually. Or by recompiling with -funroll-loops and/or -floop-unroll-and-jam.

Additional hints and workarounds are visible on the right side of the interface, including suggestions for using 'contiguous' attribute, setting 'b' to 'a' before the loop, and using AVX2 processors.

Topology Tab: Istopo View

- Hover above the « Topology » tab name to see the scrolling list allowing to select additional views to display

The diagram illustrates the Istopo view interface, which displays thread affinities and core information. The interface is divided into several sections:

- Left Panel:** Contains tabs for "Loops", "Topology", "Istopo", "Istopo_PU", and "Istopo_threads". The "Istopo" tab is selected. Below the tabs, a "Command:" field is visible, showing "OMP_PLACES: t".
- Annotations:**
 - A red box highlights the "Istopo" tab, with an arrow pointing to a text box: "Displays a graphical representation of the threads affinities and the cores on which they ran".
 - A red box highlights the "Istopo_PU" tab, with an arrow pointing to a text box: "Displays for each core a weighted list of threads that executed on this core".
 - A red box highlights the "Istopo_threads" tab, with an arrow pointing to a text box: "Displays for each thread a weighted list of the cores on which the thread executed".
- Topology View:** A large grid showing the hierarchy of threads, packages, and cores. The grid is organized into columns for "Core L#0" through "Core L#23". Each core contains a list of "PU L#" (Processing Units) and their corresponding "P#" (Process IDs). A blue box highlights the "PU L#26 P#13" entry under "Core L#13".
- PIDs Panel:** A list of process IDs on the right side of the interface. It includes a search bar and a list of threads. A red box highlights the thread "MPI #0 - OMP #0.13 - Thread 19693".
- Annotations:**
 - A red box highlights the thread "MPI #0 - OMP #0.13 - Thread 19693", with an arrow pointing to a text box: "Hover over a thread to highlight the core(s) on which it ran".

MAQAO ONE View Scalability Reports

Goal: Provide a view of the application scalability

- Profiles with different numbers of threads/processes
- Displays efficiency metrics for application

MAQAO ONE View Scalability Reports – Application View

Coverage per category

- Comparison of categories for each run

Coverage per parallel efficiency

- $$Efficiency = \frac{T_{sequential}}{T_{parallel} * N_{threads}}$$
 - Distinguishing functions only represented in parallel or sequential
- Displays efficiency by coverage

MAQAO ONE View Scalability Reports – Functions and Loops Views

Displays metrics for each function/loop

- Efficiency
- Potential speedup if efficiency=1

for each

up if efficiency=1

Performance analysis and optimisation

Where is the application spending most execution time and resources?

Why is the application spending time there?

- Algorithm, implementation, runtime or hardware?
- Data access or computation?

How to improve the application?

- At which step(s) of the workflow or dev process?
- What additional information is needed?

How much gain can be expected?

- At what cost?

MAQAO Main structure

MAQAO CQA: Main Concepts

Applications exploit at best 5 to 10% of the peak performance.

Main elements of analysis:

- Peak performance
- Execution pipeline
- Resources/Functional units

Key performance levers for core level efficiency:

- Vectorization
- Avoiding high latency instructions if possible (DIV/SQRT)
- Guiding the compiler code optimization
- Reorganizing memory and data structures layout

Same instruction – Same cost

MAQAO CQA: Guiding the compiler and implementation hints

Compilers can be driven using flags, pragmas, and keywords:

- Ensuring full use of architecture capabilities (e.g. using flag `-xHost` on AVX capable machines)
- Forcing optimizations (unrolling, vectorization, alignment, ...)
- Bypassing conservative behaviour when possible (e.g. 1/X precision)

Hints for implementation changes:

- Improve data access patterns
 - Memory alignment
 - Loop interchange
 - Changing loop strides
 - Reshaping arrays of structures
- Avoid instructions with high latency (SQRT, DIV, GATHER, SCATTER, ...)

Analysing an application with MAQAO

MAQAO modules can be invoked separately for advanced analyses

- LProf

- Profiling

```
$ maqao lprof xp=exp_dir --mpi-command="mpirun -n 16 -ppn 4" ppn=4 -- ./bt-mz.C.16
```

- Display functions profile

```
$ maqao lprof xp=exp_dir -df
```

- Displaying the results from a ONE View run

```
$ maqao lprof xp=oneview_xp_dir/tools/lprof_npsu -df
```

- CQA

```
$ maqao cqa loop=42 bt-mz.C.16
```

Online help is available:

```
$ maqao lprof --help
```

```
$ maqao cqa --help
```

Application to Motivating Example

Vectorization

Your loop is partially vectorized.
Only 28% of vector register length is used (average across all SSE/AVX instructions).
By fully vectorizing your loop, you can lower the cost of an iteration from 57.00 to 21.50 cycles (2.65x speedup).
51% of SSE/AVX instructions are used in vector version (process two or more data elements in vector registers):

- 24% of SSE/AVX loads are used in vector version.
- 0% of SSE/AVX stores are used in vector version.

Since your execution units are vector units, only a fully vectorized loop can use their full power.

Proposed solution(s):

- Try another compiler or update/tune your current one:
 - use the `vec-report` option to understand why your loop was not vectorized. If "existence of vector dependences", try the `IVDEP` directive. If, using `IVDEP`, "vectorization possible but seems inefficient", try the `VECTOR ALWAYS` directive.
- Remove inter-iterations dependences from your loop and make it unit-stride:
 - if your arrays have 2 or more dimensions, check whether elements are accessed contiguously and, otherwise, try to permute loops accordingly:
Fortran storage order is column-major: `do i do j a(i,j) = b(i,j)` (slow, non stride 1) => `do i do j a(j,i) = b(i,j)` (fast, stride 1)
 - If your loop streams arrays of structures (AoS), try to use structures of arrays instead (SoA):
`do i a(i)%x = b(i)%x` (slow, non stride 1) => `do i a%x(i) = b%x(i)` (fast, stride 1)

Execution units bottlenecks

Performance is limited by:

- execution of divide and square root operations (the divide/square root unit is a bottleneck)
- execution of INT/FP operations in vector registers (the VPU is a bottleneck)

By removing all these bottlenecks, you can lower the cost of an iteration from 57.00 to 48.00 cycles (1.19x speedup).

Proposed solution(s):

- Reduce the number of division or square root instructions.
If denominator is constant over iterations, use reciprocal (replace `x/y` with `x*(1/y)`). Check precision impact. This will be done by your compiler with `no-prec-div` or `Ofast`.
Check whether you really need double precision. If not, switch to single precision to speedup execution.
- Reduce arithmetical operations on array elements

FMA

Detected 48 FMA (fused multiply-add) operations.
Presence of both ADD/SUB and MUL operations.

Proposed solution(s):

Try to change order in which elements are evaluated (using parentheses) in arithmetic expressions containing both ADD/SUB and MUL operations to enable your compiler to generate FMA instructions wherever possible.
For instance `a + b*c` is a valid FMA (MUL then ADD).
However `(a+b)*c` cannot be translated into FMA.

Slow data structures access

Detected data structures (typically arrays) that cannot be efficiently read/written:

- Constant non-unit stride: 1 occurrence(s)
- Irregular (variable stride) or indirect: 1 occurrence(s)

7) Motivating factors:

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations
- 7) Vector vs scalar
